

PERFORMANCE TESTING

Performance Testing

Performance testing is performed to assess the speed, stability, reliability, and scalability of the Automated Network Request Management System under different usage conditions. The testing covers Service Catalog requests, request submission, record processing, approval activities, notifications, and Flow Designer execution.

1. Performance Testing Objectives

- Check application behavior during normal as well as high user activity.
- Record the response time of important request-management operations.
- Confirm that multiple requests can be handled successfully at the same time.
- Detect delays, bottlenecks, or inefficient processing areas.
- Observe utilization of available system resources during testing.
- Validate the execution time of approval and automation flows.
- Assess whether the application can support increasing request volumes.
- Maintain acceptable performance and a smooth user experience.

2. Performance Test Environment

Component	Configuration / Details
Platform	ServiceNow
Application	Automated Network Request Management
Instance	Personal Developer Instance (PDI)
Primary Interface	Service Catalog
Automation	Flow Designer
Data Storage	ServiceNow platform tables
Test Users	Multiple simulated users with concurrent activity
Test Data	Network requests, users, approvals, and catalog variables
Network	Reliable internet connection
Testing Approach	Functional performance, load, stress, and concurrency testing
